Are second-life lithium-ion batteries suitable for stationary energy storage applications?

However, there are still many issues facing second-life batteries (SLBs). To better understand the current research status, this article reviews the research progress of second-life lithium-ion batteries for stationary energy storage applications, including battery aging mechanisms, repurposing, modeling, battery management, and optimal sizing.

Are second-life batteries profitable?

Scrutiny of economic feasibility and profitable uses for second-life batteries. Examination and comparison of power electronics for second-life battery performance. Due to the increasing volume of electric vehicles in automotive markets and the limited lifetime of onboard lithium-ion batteries, the large-scale retirement of batteries is imminent.

Will second-life batteries fail?

Second-life batteries will either fail or experience exponential growth over the next 3-5 years. Retired batteries are available in increasing quantities, and there is clear demand for low-cost, stationary energy storage. Companies seeking to take advantage of the opportunity must act now, or risk missing the boat.

Should EV batteries be merged into second-life applications?

After regrouping, specific management strategies are necessary to deal with the low energy and power capabilities, large inconsistencies, and potential safety concerns when integrating retired batteries from different EVs into second-life applications.

How can we promote Second-Life batteries?

Federal and state tax credits, rebates, and other financial incentives should be offered to promote the application of second-life batteries. The availability of battery data is critical for these, and one approach to do this is by using a software in the BMS to follow the batteries from their inception.

What are the challenges to a second-life EV battery deployment?

Major challenges to second-life deployment include streamlining the battery repurposing process and ensuring long-term battery performance. By 2030, the world could retire 200-300 gigawatt-hours of EV batteries each year. A large fraction of these batteries will have 70% or more of their original energy capacity remaining.
